In the diagram classes are represented using boxes which contain three parts:

- The upper part holds the name of the class
- The middle part contains the attributes of the class
- The bottom part contains the methods or operations

# Relationships

- A relationship is a general term covering the specific types of logical connections found on class diagrams.
- A *Link* is the basic relationship among objects. It is represented as a line connecting two or more object boxes.

# Associations

Binary associations (with two ends) are normally represented as a line, with each end connected to a class box.

An association can be named, and the ends of an association can be annotated with role names, ownership indicators, multiplicity, visibility, and other properties. Association can be Bi-directional as well as uni-directional.

# Aggregation

- **Layer** - a logical structuring mechanism for the elements that make up your software solution
- A multilayered software architecture is using different layers for allocating the responsibilities of an application.
- A layer is a group of classes (or modules) that have the same set of module dependencies to other modules and are reusable in similar circumstances.

- **High Cohesion** - an evaluative pattern that attempts to keep objects appropriately focused, manageable and understandable.
- High cohesion means that the responsibilities of a given element are strongly related and highly focused.
- Breaking programs into classes and subsystems is an example of activities that increase the cohesive properties of a system.
- Alternatively, low cohesion is a situation in which a given element has too many unrelated responsibilities. Elements with low cohesion often suffer from being hard to comprehend, hard to reuse, hard to maintain and adverse to change

# Low Coupling

Assign responsibilities so that coupling remains low  
**Low Coupling** dictates how to assign responsibilities to support:

- Low dependency between classes;
- Low impact in a class of changes in other classes;
- High reuse potential

# Low Coupling

Form of coupling:

- TypeX has an attribute (field) that refers to a TypeY instance, or TypeY itself.
- TypeX has a method which references an instance of TypeY, or TypeY itself, by any means. (parameter, local variable, return value, method invocation)
- TypeX is a direct or indirect subclass of TypeY.

Assign a responsibility to the class that has the information necessary to fulfill the responsibility.

- **Information Expert** is a principle used to determine where to delegate responsibilities. These responsibilities include methods, computed fields and so on.
- Using the principle of Information Expert a general approach to assigning responsibilities is to look at a given responsibility, determine the information needed to fulfil it, and then determine where that information is stored.
- Information Expert will lead to placing the responsibility on the class with the most information required to fulfil it

- Creator pattern is responsible for creating an object of the class. In general, a class B should be responsible for creating instances of class A if one, or preferably more, of the following apply:
  - Instances of B contains or compositely aggregates instances of A
  - Instances of B record instances of A
  - Instances of B closely use instances of A
  - Instances of B have the initializing information for instances of A and pass it on creation.

## Work Items

	Task
T1	Create Student

Some assembly  
required

- When an expert violates high cohesion and low coupling
- Assign a highly cohesive set of responsibilities to an artificial class that does not represent anything in the problem domain, in order to support high cohesion, low coupling, and reuse
- **Pure Fabrication** - a class that does not represent a concept in the problem domain is specially made up to achieve low coupling, high cohesion
- Problem: Store **Student** (in memory, file or database)
- **Expert** pattern? Student is the "expert" to perform this operation

# Pure Fabrication - Repository

Some assembly  
required

- Problem: Store **Student** (in memory, file or database)
- **Expert** pattern - Student is the "expert" to perform this operation. But putting this responsibility into the Student class will result in low cohesion, poor reuse
- Solution - **Pure Fabrication**

Class created with the responsibility to store Students

The Student class easy to reuse, has High cohesion, Low coupling

Repository will deal with the problem of managing a list o students (persistent storage)

# Repository Pattern

## First create the test...

```
def tesCreateStudent():  
    """  
        Test store student  
    """  
    rep = InMemoryRepository()  
    val = StudentValidator()  
    ctr = StudentController(rep, val)  
    st = ctr.createStudent("1", "Ion", "Adr")  
    assert st.getId()=="1"  
    assert st.getName()=="Ion"  
    try:  
        st = ctr.createStudent("1", "Vasile", "Adr")  
        assert False  
    except ValueError:  
        pass  
    try:  
        st = ctr.createStudent("1", "", "")  
        assert False  
    except ValueError:  
        pass
```

# Task: create controller

- **Dependency injection** - a design pattern in object-oriented computer programming whose purpose is to reduce the coupling between software components.
- Frequently an object uses (depends on) work produced by another part of the system.
- With **DI**, the object does not need to know in advance about how the other part of the system works. Instead, the programmer provides (injects) the relevant system component in advance along with a contract that it will behave in a certain way

# Assemble everything
